Background

- Though 75% of women who smoke report wanting to quit, the vast majority are unsuccessful with only 3% quitting annually.

- Estrogen has been shown to increase the reward value of nicotine while progesterone has the opposite effect.
- Administration of exogenous progesterone may lower the body's positive response to nicotine and ease symptoms of withdrawal when attempting to quit smoking.

Goals and Objectives

- The acceptability of exogenous hormone administration as a tool for smoking cessation for women is still unknown.
- To address this gap, we explored the perception of reproductive age women who smoke with respect to willingness to use hormones as a smoking cessation tool.

Methods

Anonymous, cross-sectional online survey conducted using Prolific

Survey questions covered:

- Smoking and cessation history
- Previous hormone use (yes/no)
- Willingness to use various hormone types as a smoking cessation technique (5-point Likert scale)
 - Types (i.e., estrogen, progesterone)
 - Methods (i.e., injectable, oral, patch, insertable)
 - Lengths of effect (i.e., 1 week, 1 month, 3 months)

Eligibility Criteria:

- Self-reported daily cigarette smoker
- 18 – 40 years of age
- Assigned female at birth

Results

- Of the 461 women who responded, n=400 (96%) reported any previous hormone use.
- Average age of those who reported previous hormone use was 30.5 ± 6.1 years compared to 27.2 ± 5.7 years for those without history of hormone use (p<0.0001).
- Participants who had used hormones previously were significantly more likely to be willing to use oral hormones than women who had no history of hormone use (OR: 2.03, 95% CI: 1.01, 4.06).

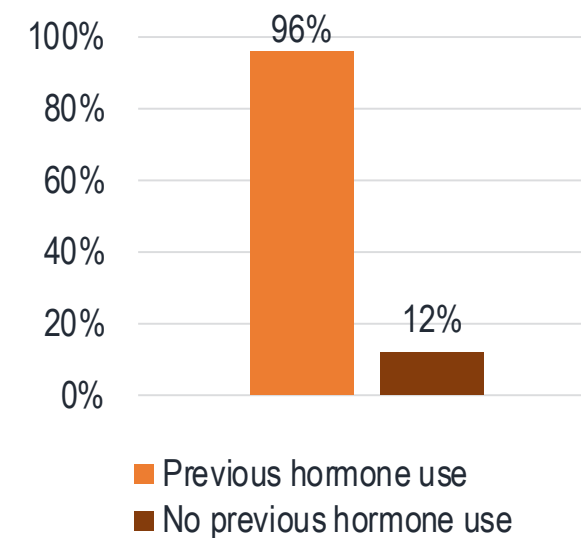

Fig 1. Willingness to use hormones as a smoking cessation aid by previous hormone use (n=247 previous hormone use; n=61 no previous hormone use).

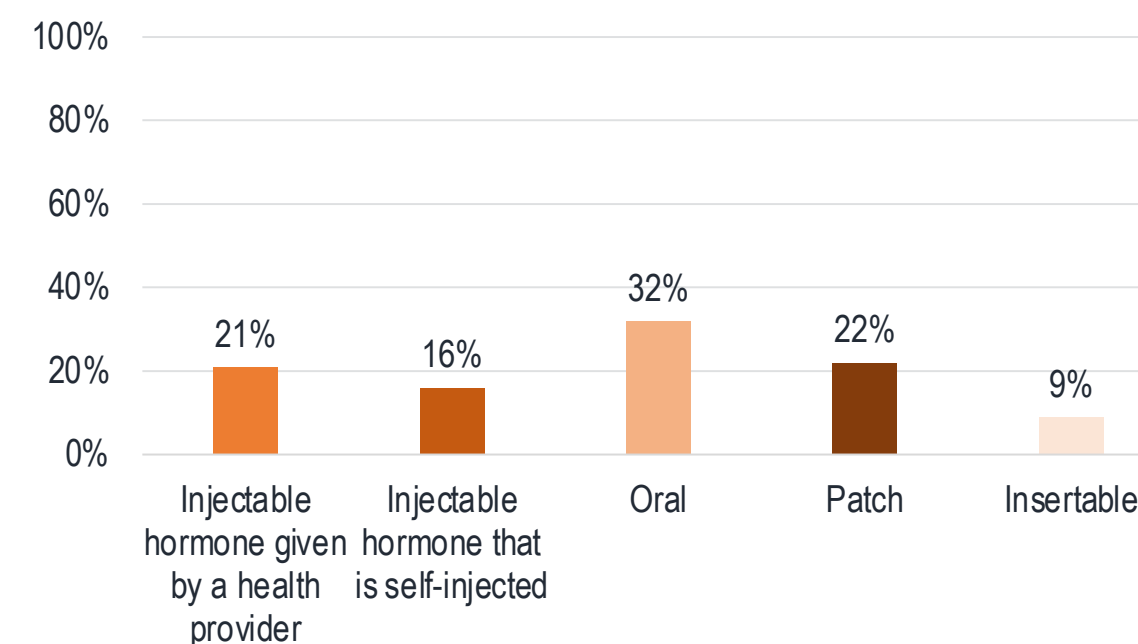

Fig 2. Willingness to use hormones as a smoking cessation aid by mode of delivery (n=215).

Conclusions

- These data indicate that most women who smoke cigarettes have a history of using hormonal contraceptives and are willing to use hormones as a smoking cessation aid.
- Limitations for this study include self-reported data and limited generalizability.
- Future interventions should explore how to incorporate exogenous hormones as a cessation tool.

Public Health Impact

- Incorporation of exogenous progesterone may increase the effectiveness of smoking cessation interventions and improve the rate of smoking cessation outcomes for women of reproductive age,
